

**Discursive analysis of itineraries  
in a historical regional corpus of travels**

***syntax, semantics & pragmatics  
in a unified  
type theoretical framework***

Richard Moot<sup>Bx</sup>, Laurent Prévot<sup>Aix</sup>, Christian Retoré<sup>Bx</sup>

**Bx:** LaBRI, INRIA, Université de Bordeaux

**Aix:** LPL Université de Provence

Providing a type theoretical frame work for a treatment from syntax to discourse (CG syntax, compositional DRT semantics, meaning transfers, discourse relations)

1. corpus and objective, the virtual traveller problem
2. categorial parser with DRS outputs
3. extending the type system for lexical pragmatics
4. a lexicon and an analysis involving a virtual traveller

No interpretation of the semantic representation.  
Faithful modelling of the linguistic analyses of motion verbs done by others.

**Part I**

# **Data, question and outline**

## 1. A case study, a field for semantic experiments

Corpus: French, XVII-XX century (mainly XIX), travel stories through the Pyrenees (576.334 words).

Goal: given some text, can we reconstruct the itinerary followed by the traveller?

More concretely: we want to transform the text into some semantic representation which allows us to infer the itinerary.

## 2. Example

- (1) Jusqu'à Langon, nous avons longé la Garonne, traversant un véritable jardin rempli de vignes et d'arbres fruitiers.

*Until Langon, we went along the Garonne, making our way through what seemed like a garden filled with vines and fruit trees.*

### 3. From parsing to semantics within type theory

- Multimodal categorial grammar
  - syntactic lexicon acquired from corpora  
Categorial grammar
  - semantic/lexicon hand written (smaller prototype)  
lambda DRT
- lexicon designed for semantics and pragmatics  
meaning transfer functions, second order lambdas
- ? finding out narration, elaboration, background relations  
SDRT
- ?? itinerary reconstruction  
spatio-temporal reasoning using our geographic data base,  
tense/aspect, etc.

To facilitate this process, we advocate the use of variable types (Girard's system F).

#### 4. A particular phenomenon: “fictive motion”

*For though it be lawful to say, for example, in common speech, the way goeth, or leadeth hither, or thither; the proverb says this or that (whereas ways cannot go, nor proverbs speak); yet in reckoning, and seeking of truth, such speeches are not to be admitted.*

Hobbes, Leviathan (1651), Chapter V, Of Reason and Science.

Many of the authors of our corpus don't follow this advice. In the cognitive literature (Talmy), the following examples are called “fictive movement”.

- (2) The path descended abruptly.
- (3) The road runs along the coast for two hours.
- (4) The fence zigzags from the plateau to the valley.
- (5) The highway crawls through the city.

This does not mean that someone actually follows the path.  
How do we model this?

## 5. Examples from our corpus

- (6) Nous coupons ici un sentier qui vient du port de Barroude (...)

*Here, we cross a path which comes from the pass of Barroude*

- (7) Plus loin, de nobles hêtres montent sur le versant (...)

*Further away, noble beeches climb the slope*

- (8) (...) cette route qui monte sans cesse pendant deux lieues

*this road which climbs incessantly for two miles*

- (9) Le chemin pavé de calcaire et de pierres luisantes (...)

*serpente à travers fourrés de buis et de noisetiers*

*The road paved with limestone and shining stones winds across buxus and hazels shrubbery*

- (10) Puis, cinq minutes nous conduisent à un petit pont (...) qui nous porte sur la rive droite.

*Afterwards, five minutes take us to a small bridge ... which carries us to the right bank.*

**Part II**

# **Categorial syntax and semantics**

## 6. Grail categorial parser and French grammar

- Grail is a general-purpose parser for (multimodal) categorial grammars.
- A wide-coverage French grammar has been semi-automatically extracted from the French Treebank.
- On the basis of the 382.145 words and 12.822 sentence of the treebank, the extraction algorithm extracts 883 different formulas, of which 664 occur more than once.
- Many frequent words are assigned *many* different formulas.
- Standard statistical methods (*supertagging*) help with lexical disambiguation.

## 7. Number of entries for common words and POS tags

et	CONJ	71		
,	PONCT	62		
à	PRP	55	ADV	206
plus	ADV	44	VERB	175
ou	CONJ	42	PRP	149
est	VERB	39	CONJ	92
être	INF	36	PONCT	89
en	PRP	34		
a	VERB	31		

## 8. Syntactic categories

Atomic categories:  $np$  (noun phrase),  $n$  (common noun),  $s$  (sentence) and  $pp$  (prepositional phrase) (the actual set of categories is slightly more detailed).

Categories:

- atomic categories
- $A/B$  whenever  $A$  and  $B$  are categories
- $B \setminus A$  whenever  $A$  and  $B$  are categories

Rules:

$$\frac{A/B \quad B}{A} / E \qquad \frac{\dots [B]}{A} / I$$

## 9. Example

- The supertagger assigns supertag with a confidence level (indicated by the darker blue part of the square before the formula)
- when it is less sure it proposes more alternatives
- Most words only have a single formula is proposed by the supertagger, the verb “monte” (which does not occur at all in the training corpus) has three possible formulas and the preposition “pendant” has two.

## 10. Semantics

- Categorical derivations (being a proper subset of derivations in multiplicative intuitionistic linear logic) correspond to (simply typed) linear lambda terms.
- This makes the connection to Montague grammar particularly transparent.

$$\frac{A/B : f^{U \rightarrow T} \quad B : x^U}{A : (f x)^T} /E$$

$$\dots [B : x^U]$$

$$\vdots$$

$$\frac{A : t^T}{A/B : \lambda x^U t} /I$$

## 11. Language, Metaphysics and Ontology

### Metaphysics

- What is there?
- What kind of things are there and how are they related?

### Natural Language Metaphysics Bach (1986)

- What do people talk as if there is?
- What kinds of things and relations along them does one need in order to exhibit the structural of meanings that natural languages seem to have?

### But...

"We have learned to be weary, however, of what the surface of language suggests, especially when it comes to ontology"  
Davidson (1970)

## 12. Different sorts

Montague: one type of entity  $e$ .

*“although there may be real metaphysical doubts whether the Great Pyramid and the Battle of Waterloo are fundamentally different in kind, natural language seems to advise us that they are different”* Bach (1986)

Many syntactically well-formed sentences are semantically ill-formed in a way which is more easily and better modeled by using different sorts ( $Ty_n$ , Gallin Muskens).

(11) The Battle of Waterloo took place on Sunday 18 June 1815.

(12) # The Great Pyramid took place on Sunday 18 June 1815.

If we distinguish between events and physical objects we can say that sentence 12 is nonsense (instead of simply false).

## 12.1. Events

Davidson (1967) looks at sentences such as the following

(13) Brutus stabbed Caesar with a knife on the Ides of March.

(14) The stabbing of Ceasar (with a knife) by Brutus took place on the Ides of March.

and proposes to analyse them as follows (where  $e$  is a variable denoting an event)

$$\exists e.stab(e, Brutus, Caesar) \wedge with(e, knife) \wedge date(e, IdesofMarch)$$

This, as he notes, has the pleasant consequence that the following formulas are all *derivable* from this semantic representation.

$$\vdash \exists e.stab(e, Brutus, Caesar) \wedge with(e, knife)$$
$$\vdash \exists e.stab(e, Brutus, Caesar) \wedge date(e, IdesofMarch)$$
$$\vdash \exists e.stab(e, Brutus, Caesar)$$

## 12.2. Other sorts

Besides events/eventualities, we use several other types of entities including:

- locations
- paths
- physical objects
- information

It's a flat ontology (but we'll come back to that)

### 12.3. No Entity Without Identity...

Quine (1969) famously said “no entity without identity”.

How do we decide whether or not two events are identical?

On the other hand, the ship of Theseus (as reported by Plutarch) and the river of Heraclitus show that identity for physical objects is not so easy either.

*“We must not try to resolve the metaphysical questions first, and then construct a meaning-theory in the light of the answers. We should investigate how our language actually functions, and how we can construct a workable systematic description of how it functions; the answers to those questions will then determine the answers to the metaphysical ones.”*

Dummet (1991, p. 338)

### 13. Semantics with lambda-DRT

We use a  $\lambda$ -DRT entities/individuals divided into several sorts  $T_{y_n}$ .

Extension to  $TY_n$  without difficulty nor surprise:  $e$  can be divided in several kind of entities.

Let us show an example of a lexicon, and the treatment of an example.

$\oplus$  is the DRS merge operation.

All movement verbs are analysed with a three argument predicate  $travel(e, x, p)$ , where  $e$  is a movement event,  $x$  is the moving physical entity (typically a person) and  $p$  is a path.

word phrase syntactic type	lambda-DRS		
<i>descend</i> <i>np\s</i>	$\lambda x^{person} \lambda e^{event}$ <table border="1" data-bbox="836 253 1317 450"><tr><td data-bbox="836 253 1317 305"><math>p^{path}</math></td></tr><tr><td data-bbox="836 305 1317 450"><math>travel(e, x, p)</math> <math>height(source(p))</math> <math>&gt; height(destination(p))</math></td></tr></table>	$p^{path}$	$travel(e, x, p)$ $height(source(p))$ $> height(destination(p))$
$p^{path}$			
$travel(e, x, p)$ $height(source(p))$ $> height(destination(p))$			
<i>Jean</i> <i>s/(np\s)</i>	$\lambda p^{person \rightarrow event \rightarrow t} \lambda e^{event}$ <table border="1" data-bbox="967 538 1131 637"><tr><td data-bbox="967 538 1131 585"><math>y^{person}</math></td></tr><tr><td data-bbox="967 585 1131 637"><i>Jean</i>(y)</td></tr></table> $\oplus ((P y) e)$	$y^{person}$	<i>Jean</i> (y)
$y^{person}$			
<i>Jean</i> (y)			

## 14. Syntactic / semantic analysis

Syntactic analysis is proving

$Jean\ descend \vdash s \dots$

and it tells us that the semantic is the application of the semantic  $\lambda$ -term of *Jean* to the one of *descend*

$$\left( (\lambda P^{person \rightarrow event \rightarrow t} \lambda e^{event} \begin{array}{|l|} \hline y^{person} \\ \hline \end{array} \oplus ((P\ y)\ e)) \right.$$

$$\left. \lambda x^{person} \lambda e^{event} \begin{array}{|l|} \hline p^{path} \\ \hline \text{travel}(e, x, p) \\ \text{height}(\text{source}(p)) \\ > \text{height}(\text{destination}(p)) \\ \hline \end{array} \right)$$

$\rightarrow \beta$

$$\lambda e^{\text{event}} \begin{array}{|l} y^{\text{person}} \\ \hline \text{Jean}(y) \end{array} \oplus \left( (\lambda x^{\text{person}} \lambda e^{\text{event}} \begin{array}{|l} p^{\text{path}} \\ \hline \text{travel}(e, x, p) \\ \text{height}(\text{source}(p)) \\ > \text{height}(\text{destination}(p)) \end{array}) y \right)$$

$\rightarrow \beta$

$$\lambda e^{\text{event}} \begin{array}{|l} y^{\text{person}} \\ \hline \text{Jean}(y) \end{array} \oplus \left( (\lambda e^{\text{event}} \begin{array}{|l} p^{\text{path}} \\ \hline \text{travel}(e, y, p) \\ \text{height}(\text{source}(p)) \\ > \text{height}(\text{destination}(p)) \end{array}) e \right)$$

$\rightarrow \beta$

$\lambda e^{\text{event}}$	$y^{\text{person}}$	$\oplus$	$p^{\text{path}}$
	<i>Jean(y)</i>		<i>travel(e, y, p)</i> <i>height(source(p))</i> <i>&gt; height(destination(p))</i>

→ DRS merge

$\lambda e^{\text{event}}$	$y^{\text{person}}$	$p^{\text{path}}$
	<i>Jean(y)</i>	<i>travel(e, y, p)</i> <i>height(source(p)) &gt; height(destination(p))</i>

→ Existential closure

$e^{event} \quad y^{person} \quad p^{path}$

*Jean*( $y$ )

*travel*( $e, y, p$ )

*height*(*source*( $p$ ))

> *height*(*destination*( $p$ ))

Part III

## Extending the type system:

$\wedge T_{y_n}, F-DRT$

## 15. Second order types (Girard's F).

$T_{y_n}$  (several base types) filters the sort of the argument according to lexical constraints, but...

uniform operations on all terms of all types are useful.

For co-predication, for (generalized) quantification, and all operation that act uniformly upon all types, one can also add type variables and quantification over types.

**16. More general types and terms.  
Second order types (Girard's F).**

- Constants  $e$  (or  $e_1, \dots, e_n$  in a multisorted system) and  $t$ , as well as any type variable  $\alpha$  in  $P$ , are types.
- Whenever  $T$  is a type and  $\alpha$  a type variable which may but need not occur in  $T$ ,  $\Pi.\alpha. T$  is a type.
- Whenever  $T_1$  and  $T_2$  are types,  $T_1 \rightarrow T_2$  is also a type.

## 17. More general types and terms. Second order terms (Girard's F).

- A variable of type  $T$  i.e.  $x : T$  or  $x^T$  is a *term*.  
Countably many variables of each type.
- $(f \tau)$  is a term of type  $U$  whenever  $\tau : T$  and  $f : T \rightarrow U$ .
- $\lambda x^T. \tau$  is a term of type  $T \rightarrow U$  whenever  $x : T$ , and  $\tau : U$ .
- $\tau\{U\}$  is a term of type  $T[U/\alpha]$  whenever  $\tau : \Lambda\alpha. T$ , and  $U$  is a type.
- $\Lambda\alpha. \tau$  is a term of type  $\Pi\alpha. T$  whenever  $\alpha$  is a type variable, and  $\tau : T$  without any free occurrence of the type variable  $\alpha$ .

## 18. More general types and terms. Second order reduction.

The reduction is defined as follows:

- $(\lambda\alpha.\tau)\{U\}$  reduces to  $\tau[U/\alpha]$  (remember that  $\alpha$  and  $U$  are types).
- $(\lambda x.\tau)u$  reduces to  $\tau[u/x]$  (usual reduction).

## 19. Remarks: system F

- used for the syntax of semantics (a.k.a. metalogic, glue logic)
- the formulae of semantics are the usual ones
- a single constant, e.g. for the quantifier  $\forall$  or the choice function  $\iota$  which is specialized for each type
- less types (constrained) than formulae with a free variable

It is also the type system of the polymorphic functional programming languages ML, CaML,...

## 20. More general types and terms. A second order example.

Given two predicates  $P^{\alpha \rightarrow t}$  and  $Q^{\beta \rightarrow t}$

over entities of respective kinds  $\alpha$  and  $\beta$   
when we have two morphisms from  $\xi$  to  $\alpha$  and to  $\beta$   
we can coordinate entities of type  $\xi$ :

$$\Lambda \xi \lambda x^\xi \lambda f^{\xi \rightarrow \alpha} \lambda g^{\xi \rightarrow \beta} . (\text{and } (P (f x)) (Q (g x)))$$

One can even quantify over the predicates  $P, Q$  and the types  
 $\alpha, \beta$  to which they apply:

$$\Lambda \alpha \Lambda \beta \lambda P^{\alpha \rightarrow t} \lambda Q^{\beta \rightarrow t} \Lambda \xi \lambda x^\xi \lambda f^{\xi \rightarrow \alpha} \lambda g^{\xi \rightarrow \beta} . (\text{and } (P (f x)) (Q (g x)))$$

**Part IV**

# **The theoretical lexicon at work: the virtual traveller**

## 21. Dot objects

Several words can have multiple incompatible sorts. The most famous example of Pustejovsky (1995) is the book, which is both a physical object (and therefore can be picked up and be heavy) and information (and therefore something which can be interesting or easy to read).

Examples like the following

(15) This book is heavy but interesting.

argue against a naive “lexical ambiguity” approach: which would incorrectly analyse sentence 15 as incoherent.

$$\lambda x^P(\textit{book } x)$$
$$\lambda x^i(\textit{book } x)$$
$$\lambda P^{P \rightarrow t} \lambda x^P(\textit{heavy } x) \wedge (P x)$$
$$\lambda P^{i \rightarrow t} \lambda x^i(\textit{interesting } x) \wedge (P x)$$

## 22. A Type-Theoretic Solution

A more appropriate solution is to say that there is a functional correspondance between the book as a physical object and its information content — this seems quite reasonable: children learn this function at school, and OCR software goes a long way towards implementing this function.

$$\lambda x^P(\text{book } x)$$

$$\lambda P^{P \rightarrow t} \lambda x^i ((f^{(P \rightarrow t) \rightarrow (i \rightarrow t)} P) x)$$

This is essentially the solution of Bassac, Mery and Retoré (2010) and Mery (2011): a lexical entry can specify some optional transformations which change the sortal information of the lambda term assigned to a word.

## 23. More dot-objects and copredications

See Asher (2011) for discussion and many more examples.

(16) Lunch was delicious but took forever. (food + event)

(17) I saw the Colosseum in my tourist guide and wanted to go there. (anaphor: artifact + place)

(18) The road was built in 1825 and runs from the Regent's residence at Carlton house to All Souls Church. (artifact + path)

Other examples are less good.

(19) ? Barcelona organized the 1992 olympics and won the 2010-2011 Champions League (local government + football club)

(20) # Barcelona is the capital of Catalunya and won the 2010-2011 Champions League.

(21) # Washington borders the Potomac and attacked Iraq.

## 24. Principles of our lexicon

- Remains within realm of Montagovian compositional semantics (though possibly without possible worlds semantics).
- Allows both predicate and argument to contribute lexical information to the compound.
- Works with  $\lambda$ -DRT.

We advocate a system based on *optional modifiers* which can account for lexical idiosyncrasies.

*Second-order typing*, like Girard's F system is needed for arbitrary modifiers:

$$\Lambda \alpha \lambda x^A y^{\alpha} f^{\alpha \rightarrow R} . ((\text{read}^{A \rightarrow R \rightarrow t} x) (f y))$$

## 25. A lexical entry

- syntactic category  $x$
- A standard  $\Lambda$ -term of type  $x^*$  attached to the main sense:
  - Used for compositional purposes
  - Comprising detailed typing information
  - Including slots for optional modifiers
- several  $\Lambda$ -terms modifiers (type changes), that can be:
  - rigid** the same modifier applies once for every occurrence.  
(blocks impossible copredications)
  - flexible** modifier: a different modifier can be used for each occurrence.

## 26. Rules

$$\frac{A/B : f^{U \rightarrow T} \quad B : x^U}{A : (fx)^T} /E$$

$$\begin{array}{c} \dots [B : x^U] \\ \vdots \\ A : t^T \\ \hline A/B : \lambda x^U t \quad //I \end{array}$$

$$\frac{A/B : f^{\Pi \alpha. U[\alpha] \rightarrow T} \quad B : x^{U[V]}}{A : (f\{V\}x)^T} /E^*$$

Correspondence: syntactic rule / semantic counterpart.

Instantiation and application are combined. The function only partly specifies its argument. Thereafter *le* is an instance of this process.

## 27. Specialised Lexical Semantics

A rather minimal and schematic model.

Base types *region* and *path*

- cognitively motivated (Jackendoff)
- linguistically motivated (some verbs require one).

*height* is a function from regions to their vertical coordinate.

Functions *source* and *destination*: they convert a path  $p$  to its source region and its destination region.

Predicate *middle*( $p, r$ ) where  $p$  is a path and  $r$  a region  $\rightarrow$  distinction between Initial, Median and Final verbs as in Asher an Sablayrolles

Spatial variable *here* position and orientation of the spatial reference point not necessarily the narrators's place, implemented as a succession of values.

Motion verbs: relations between one or more entities and a *path* (possibly implicit)

Verbs specify lexically which of their arguments follow this path (subject, object or both, see e.g. Nam).

The lexicon specifies which transformations can take place, allowing us to account for contrasts in grammaticality such as the following.

(22) The road leads us to Pau.

(23) \*The road accompanies us to Pau.

## 28. A lexicon

word/phrase syntactic type	lambda-term				
<i>chemin</i> <i>n</i>	$\lambda x^{immobile\_object}$ <table border="1" style="display: inline-table; vertical-align: middle;"> <tr><td> </td></tr> <tr><td><i>chemin(x)</i></td></tr> </table>		<i>chemin(x)</i>		
<i>chemin(x)</i>					
<i>g</i> <i>n/n</i>	$\lambda P^{immobile\_object \rightarrow t} \lambda p^{path}$ <table border="1" style="display: inline-table; vertical-align: middle;"> <tr> <td> <math>x^{immobile\_object} \ q^{path} \ here^{region}</math> </td> <td><math>\oplus (P \ x)</math></td> </tr> <tr> <td colspan="2"> <i>path_of(y, p)</i>  <i>subpath(q, p)</i>  <i>source(q) = here</i> </td> </tr> </table>	$x^{immobile\_object} \ q^{path} \ here^{region}$	$\oplus (P \ x)$	<i>path_of(y, p)</i> <i>subpath(q, p)</i> <i>source(q) = here</i>	
$x^{immobile\_object} \ q^{path} \ here^{region}$	$\oplus (P \ x)$				
<i>path_of(y, p)</i> <i>subpath(q, p)</i> <i>source(q) = here</i>					

*chemin*  
*n*

$\lambda x^{immobile\_object}$

<i>chemin</i> ( <i>x</i> )

---

“chemin” is true of entities of type immobile object for which *chemin*(*x*) holds

$g$   
 $n/n$

$$\lambda p^{\text{immobile\_object} \rightarrow t} \lambda p^{\text{path}} \left[ \begin{array}{l} x^{\text{immobile\_object}} \quad q^{\text{path}} \quad \text{here}^{\text{region}} \\ \text{path\_of}(y, p) \\ \text{subpath}(q, p) \\ \text{source}(q) = \text{here} \end{array} \right] \oplus (P \ x)$$

coercion  $g$ : from an immobile object  $x$  to a path  $p$ , correspondence indicated by the predicate *path\_of*

and selecting a sub-path  $q$  of  $p$  going forward from *here*, which may or may not go to the end of the path  $p$ .

both  $x$  (immobile) and  $p$  (path) are DRT referents. Indeed, both aspect can be used “a brick road to Pau” and anaphors can refer to either aspect.

(24) The street was completed in 1825 (...)

(25) It runs from the Regent’s residence at Carlton House (...) to All Souls Church.

*le*  
(*s/(np\s)/n*)

$\Lambda\alpha\lambda P^{\alpha\rightarrow t}\lambda Q^{\alpha\rightarrow event\rightarrow t}\lambda e^{event}$

$x^\alpha$

$\oplus (P\ x) \oplus ((Q\ x)\ e)$

"Le" is viewed as a generalised quantifier. It selects a noun (subset of  $\alpha$ ) and a VP which applies to  $\alpha$  to produce a sentence.

<p><i>descend</i> <i>np\s</i></p>	<p><math>\lambda x^{person} \lambda e^{event}</math></p> <table border="1" style="margin-left: 20px;"> <tr> <td style="padding: 2px;"><math>p^{path}</math></td> </tr> <tr> <td style="padding: 2px;"><math>travel(e, x, p)</math></td> </tr> <tr> <td style="padding: 2px;"><math>height(source(p)) &gt; height(destination(p))</math></td> </tr> </table>	$p^{path}$	$travel(e, x, p)$	$height(source(p)) > height(destination(p))$
$p^{path}$				
$travel(e, x, p)$				
$height(source(p)) > height(destination(p))$				
<p><i>h</i> <i>(np\s)/(np\s)</i></p>	<p><math>\lambda p^{person \rightarrow event \rightarrow t} \lambda p^{path} \lambda e^{event}</math></p> <table border="1" style="margin-left: 20px;"> <tr> <td style="padding: 2px;"><math>x^{person}</math></td> <td rowspan="2" style="padding: 2px;"><math>\Rightarrow ((P x) e)</math></td> </tr> <tr> <td style="padding: 2px;"><math>travel(e, x, p)</math></td> </tr> </table>	$x^{person}$	$\Rightarrow ((P x) e)$	$travel(e, x, p)$
$x^{person}$	$\Rightarrow ((P x) e)$			
$travel(e, x, p)$				

“descend” main term:  
 given a person argument  $x$  and an event argument  $e$ ,  
 the DRS checks that there exists a path  $p$  such that  $x$  follows  
 $p$  and that the height at the start of this path  $p$  is greater than  
 his height at the end of it.

What about coercion?

The coercion  $h$  (for “descend” but not for any motion verb) applied to *descend* yields if a person follows the path  $p$ , then he descends.

Note that “h descend” does not commit us to concluding that anyone actually takes the path. This must be deduced separately.

$le\{path\} (g\ chemin)$   
 $s/(np\backslash s)$

$\lambda p\ path \rightarrow event \rightarrow t\ \lambda e\ event$

$y^{immobile\_object}\ p^{path}\ q^{path}\ here^{region}$

$chemin(y)$

$path\_of(y, p)$

$subpath(q, p)$

$source(q) = here$

"le chemin" with type assignment  $np - \iota x^{immobile\_object}.chemin(x)$   
does not combine with "descend" which requires a person  
as its argument,  $np\backslash s - \lambda y^{person} \dots$

Both “chemin” and “descend” permit lexically anchored type coercions, which solves the type mismatch:

- “chemin” has a lexical lambda term  $g$  which coerces it in such a way that “le chemin” obtains type assignment  $np - \lambda x^{path}.chemin(x)$
- whereas “descend” has a lexical lambda term  $h$  which coerces its lexical semantics to  $np \setminus s - \lambda y^{path} \dots$
- With both coercions “le chemin descend” is a correctly typed term, with “le chemin” being a term of type  $path$  and “descend” a term of type  $path \rightarrow t$ .

## 29. Two remarks

variable *here* (place + orientation)

no incoherence between “le chemin monte” and “le chemin descend” (reversed orientation)

“pendant deux heures” simple Davidsonian analysis: the duration of the corresponding event is two hours.

$pendant\ 2\ h.\ \lambda_{s\setminus s}^{event\rightarrow t}\lambda_{e\setminus e}^{event}(s\ e)\oplus$

$duration(e, 2h)$

## 30. Some reflections

- System F is a very simple — but powerful — extension to the simply typed lambda calculus. This speaks in favor of our approach, provided we can account for the same data as Asher (2011).
- Do we need subtyping? A flat ontology seems rather unsatisfactory. However, coherently extending system F with subtyping is not straightforward.
- System F plus subtyping plus restricted quantification over subtypes of a type?

**Part V**

# **Towards Segmented Discourse Representation Structures**

## 31. Objective

Finding discourse relations,

- in particular *narration* and *elaboration* for the itinerary
- others, to skip what is irrelevant.

## 32. Some phenomena

- (26) nous descendons, pendant un quart d'heure, la vallée de l'Esera.  
*we descend, for a quarter of an hour, the Esera valley.*
- (27) La lune, qui éclaire notre marche, nous fait découvrir sur la droite un sentier qui serpente.  
*The moon, which lightens our steps, allows us to discover a winding path on our right.*
- (28) Il nous conduit sur un petit plateau, au milieu de sapins, au-dessus et à quelque distance du torrent de Ramun.  
*It leads us to a small plateau, surrounded by firs, at some distance of and above the Ramun torrent.*

“Il” (it) in sentence 28 refers to “un sentier qui serpente”  
imposes anaphora resolution before coercion.

Constraints on the possible interpretations *Background*(26,27) and *Narration*(27,28).

### 33. Examples, yet other remarks

Rhetorical structure: important but hard to infer.

- (29) Nous partimes pour Barèges à 8 heures du matin par une fort jolie route qui nous conduisit à Lourdes.  
*We left (PS) for Barèges at 8 in the morning, taking a very pretty road which led (PS) us to Lourdes.*
- (30) (...) qui va en se resserrant jusqu'à Pierrefite, où les routes de Lux et de Cauterets séparent.  
*(...) which goes shrinking along the way, up to Pierrefite, where the roads to Lux and to Cauterets split.*
- (31) Celle de Lux entre dans une gorge qui vous mène au fond d'un précipice et traverse le gave de Pau.  
*The one to Lux enters a gorge which leads you to the bottom of a precipice and traverses the Gave de Pau.*
- (32) (...) Après une longue marche, l'on arrive à Barèges à 6 heures du soir.  
*(...) After a long walk, we arrive in Barèges at 6 in the evening.*

29 introduces the destination and therefore the whole spatio-temporal extension route. The following will therefore constitute an

Elaboration relation between this sentence and the sequence of 30-32.

It is (at first sight) difficult to decide on the discourse relation of

Sentence 31: it would certainly be possible to have a later phrase beginning with “Celle de Cauterets” (the road leading to Cauterets) and a number of the following sentences (omitted here for space reasons) give further background information about the road to Lux.

However, at sentence 32, it suddenly becomes evident that the author has been describing the road while following it.

## 34. Conclusions and Future Work

Model of “virtual movement” in a type-logical grammar by extending Montague-style semantics

- DRT
- Generative Lexicon

Using system F for varying types and flexibility when it is lexically allowed.

Implementation of coercion in a prototype by Emeric Kien.

Open (common) problems

- anaphora resolution
- determining the appropriate discourse relations between segments of text

Suppressing DRS who are not relevant to the itinerary question (comparison, reason why they acted that way).
